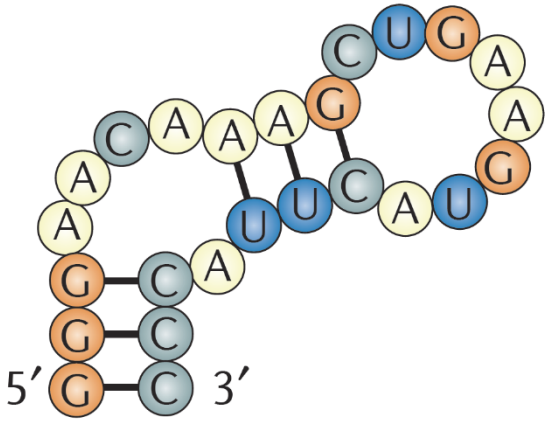
Aptamers as antibody alternatives: advances and applications

Journal Club – Lukas Frick

18 June 2019

What are aptamers?

Aptamers are **single-stranded oligonucleotides** (RNA or DNA) that fold into defined **3D structures** and recognize their target by their complementary **shape and charge**.



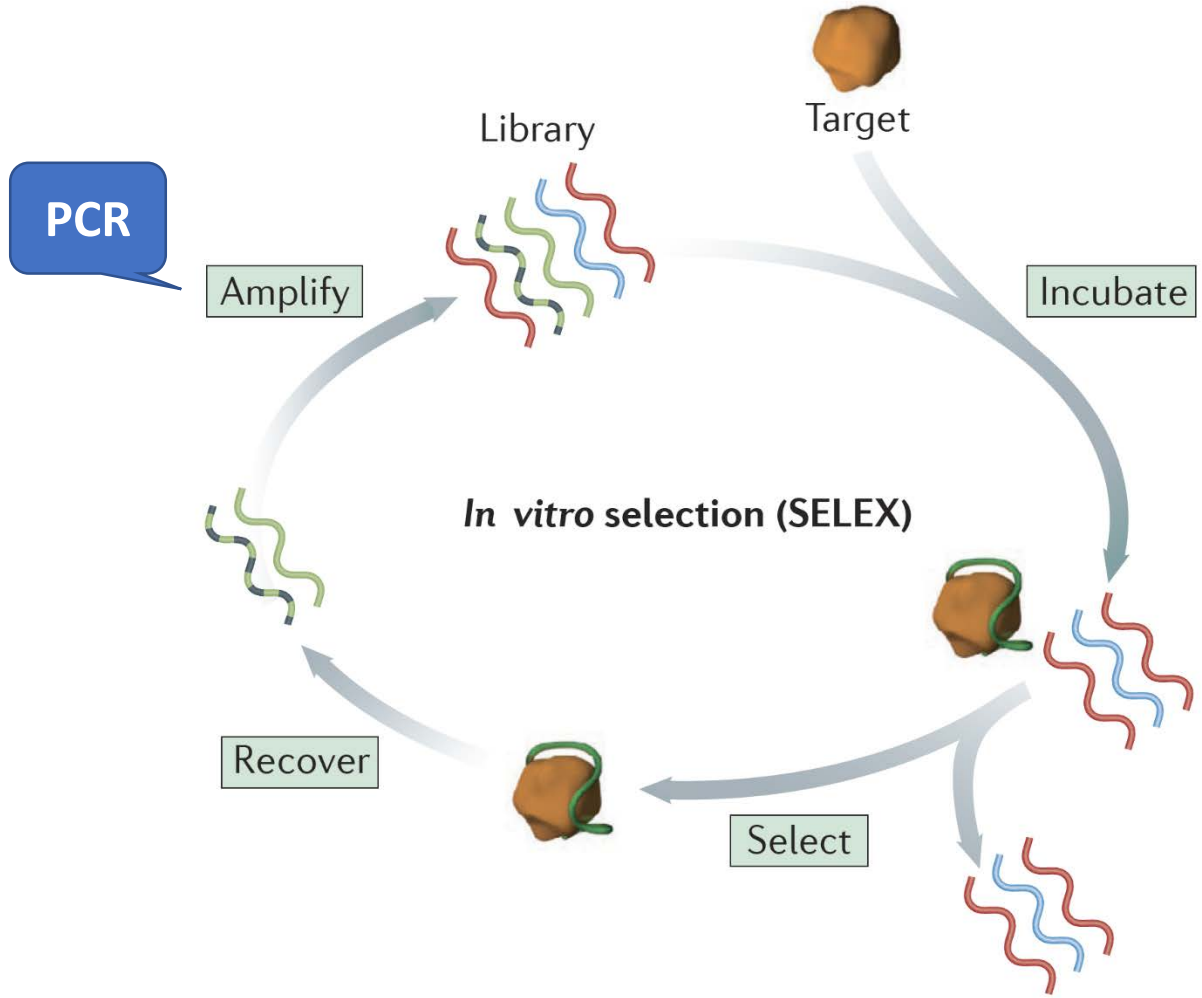
Secondary structure

Human α-thrombin-aptamer complex

Aptamers are generated artificially using some form of **SELEX**

(systematic **e**volution of **l**igands by **ex**ponential enrichment)

- The starting point is a **huge library of random oligonucleotide species** (~10^{15}).
- Aptamers with the desired properties are **enriched** by multiple (~10) rounds of **selection, then amplification.**



Aptamers and SELEX were invented 30 years ago

***In vitro* selection of RNA molecules that bind specific ligands**

***Nature*, 1990**

Systematic Evolution of Ligands by Exponential Enrichment: RNA Ligands to Bacteriophage T4 DNA Polymerase

CRAIG TUERK AND LARRY GOLD

***Science*, 1990**

Since then, many small-protein antibody mimetics have been developed…

Antibody mimetic	Scaffold	Mass
Affibody molecules	Z domain of Protein A (Staph. aureus)	6 kDa
Affilins	Gamma-B crystallin	20 kDa
	Ubiquitin	10 kDa
Affimers	Cystatin	12–14 kDa
Affitins	Sac7d (from *Sulfolobus acidocaldarius*)	7 kDa
Alphabodies	Triple helix coiled coil	10 kDa
Anticalins	Lipocalins	20 kDa
Avimers	A domains of various membrane receptors	9–18 kDa
DARPins	Ankyrin repeat motif	10–19 kDa
Fynomers	SH3 domain of Fyn	7 kDa
Kunitz domain peptides	Kunitz domains of various protease inhibitors	6 kDa
Monobodies	10th type III domain of fibronectin	10 kDa
nanoCLAMPs	Carbohydrate Binding Module 32-2 (C. *perfringens*)	16 kDa

For comparison: **aptamers are 8 – 30 kDa**

In vitro selection of proteins requires a link to the encoding sequence using:

- **Phage display**
- **Ribosome display**

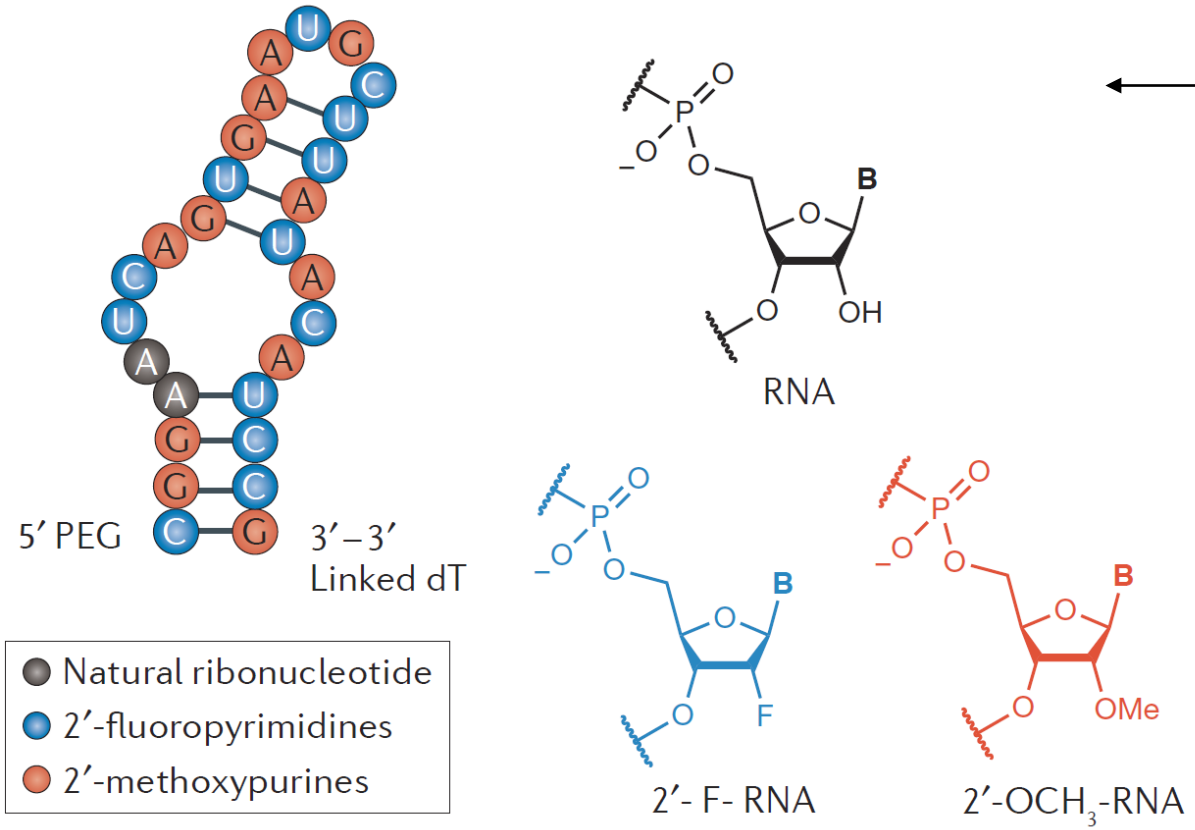
Advantages of aptamers

- Can be **chemically synthesized**
  - **Cheap**
  - **No batch-to-batch variability**
- Easy to chemically modify (fluorophores, biotin, etc.)
- Stable at room temperature
  - Refold after heat denaturation
- All technologies developed for DNA/RNA automatically apply to aptamers!
  - Next-gen sequencing, qPCR…

Disadvantages of aptamers

- **Limited diversity** of natural nucleic acids
  - For example, GFP is poorly aptagenic
- Nuclease sensitivity
  - ↓ stability in vivo

Pre- and post-SELEX modifications can increase aptamer stability



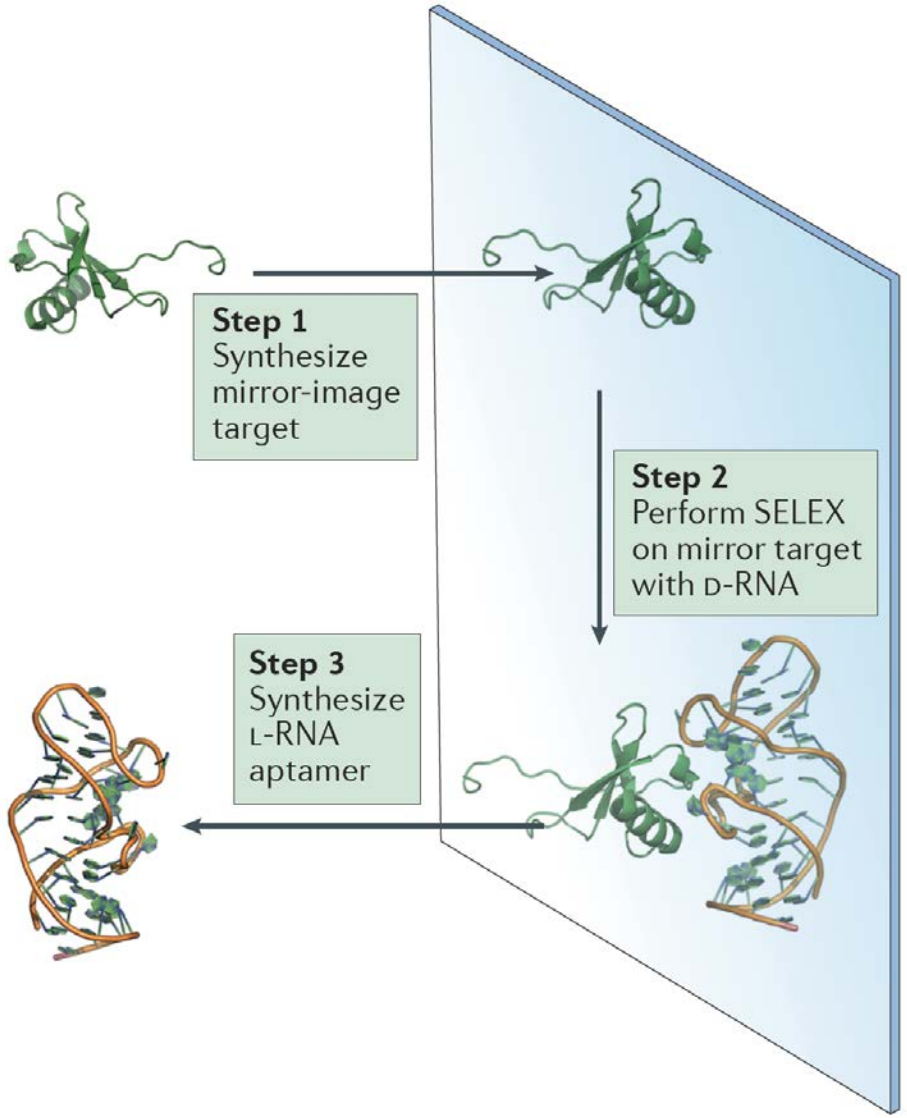
5’ polyethylene glycol (PEG)

3’ inverted nucleotide

Macugen (pegaptanib) is an anti-VEGF RNA aptamer approved for treating neovascular age-related macular degeneration (2004 in US, 2005 in Europe).

Ultimately, anti-VEGF antibodies (e.g. ranibizumab) proved more effective.

Spiegelmers made of L-enantiomer RNAs are resistant to nucleases



- Mirror-image proteins must be chemically synthesized from D-amino acids.
- SELEX is done with natural L-nucleic acids.
- In the future, mirror-image polymerases may allow SELEX with R-nucleic acids.
- Xenonucleic acids may offer another futuristic solution.

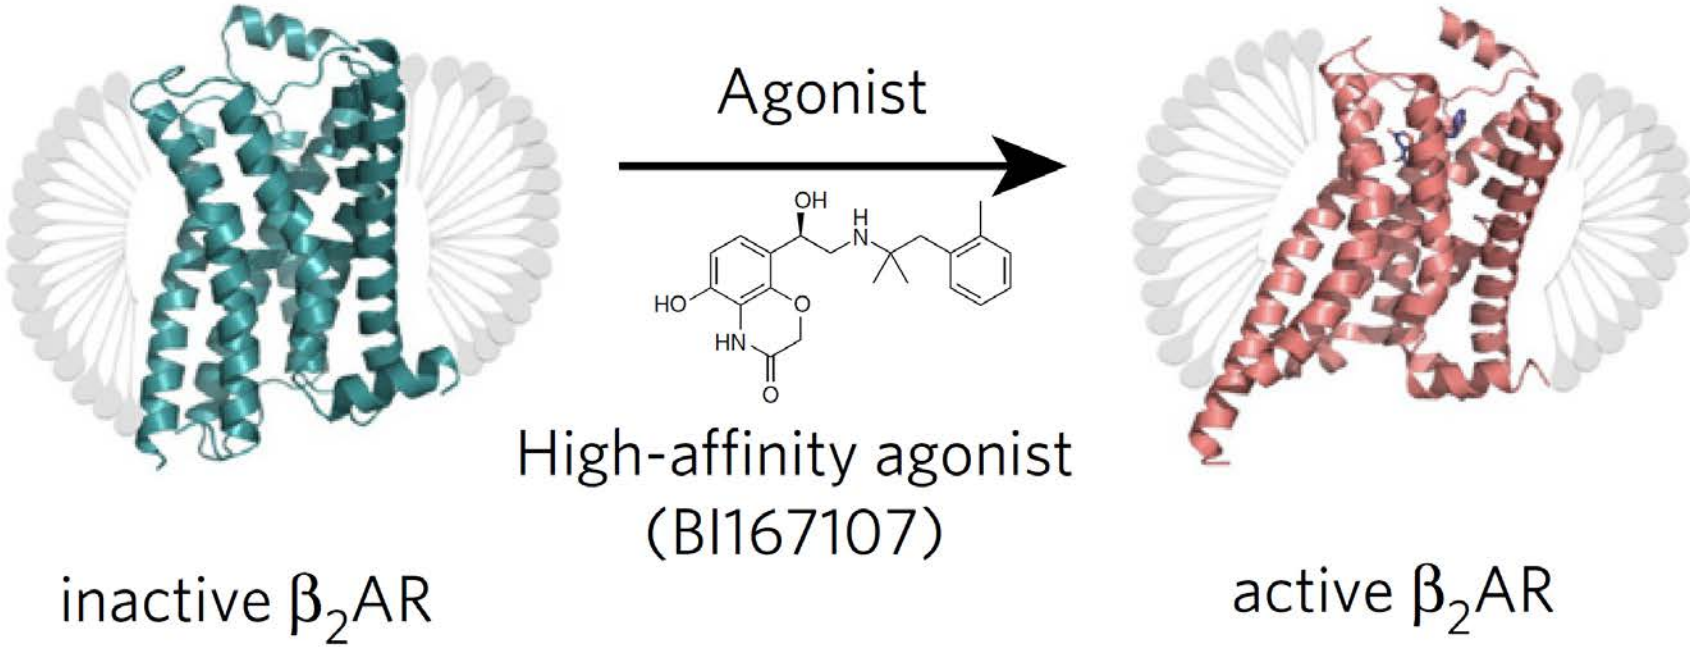
Conformationally selective RNA aptamers allosterically modulate the β_2-adrenoceptor

Alem W Kahsai[1], James W Wisler[1], Jungmin Lee[1,2], Seungkirl Ahn[1], Thomas J Cahill III[1,3], S Moses Dennison[4], Dean P Staus[1], Alex R B Thomsen[1], Kara M Anasti[4], Biswaranjan Pani[1], Laura M Wingler[1], Hemant Desai[5], Kristin M Bompiani[6–8], Ryan T Strachan[9], Xiaoxia Qin[10], S Munir Alam[4], Bruce A Sullenger[6,7] & Robert J Lefkowitz[1,3,11]*

Aptamers were developed either against the ligand-bound/active or unbound/inactive form of β_2-adrenoceptor



Why develop aptamers against β_2-adrenoceptor?

- GPCRs have complex conformational states
  - Multiple active and inactive conformations
  - Specific conformations → biased signalling (G protein vs. β-arrestin)
  - Aptamer allosteric modulators may be **useful drugs**

- Stabilization of the active conformation permits crystallography

Structure of a nanobody–stabilized active state of the β_2 adrenoceptor

Rosenbaum[1], Foon Sun Thian[1], Tong Sun Kobilka[1], Andreas Schnapp[6], Ingo Konetzki[6], Roger K. Sunahara[8], Samuel H. Gellman[7], Alexander Pautsch[6], Jan Steyaert[4,5], William I. Weis[1,3] & Brian K. Kobilka[1]

Nature, 2011

β_2AR was used as a well-characterized "model GPCR"

- Protein expression:
  - SF9 insect cells transfected with β_2AR baculovirus
  - N-terminal FLAG tag
- Protein purification:
  3-step affinity chromatography, with anti-FLAG antibodies and an **alprenerol** affinity purification step

inactive β_2AR

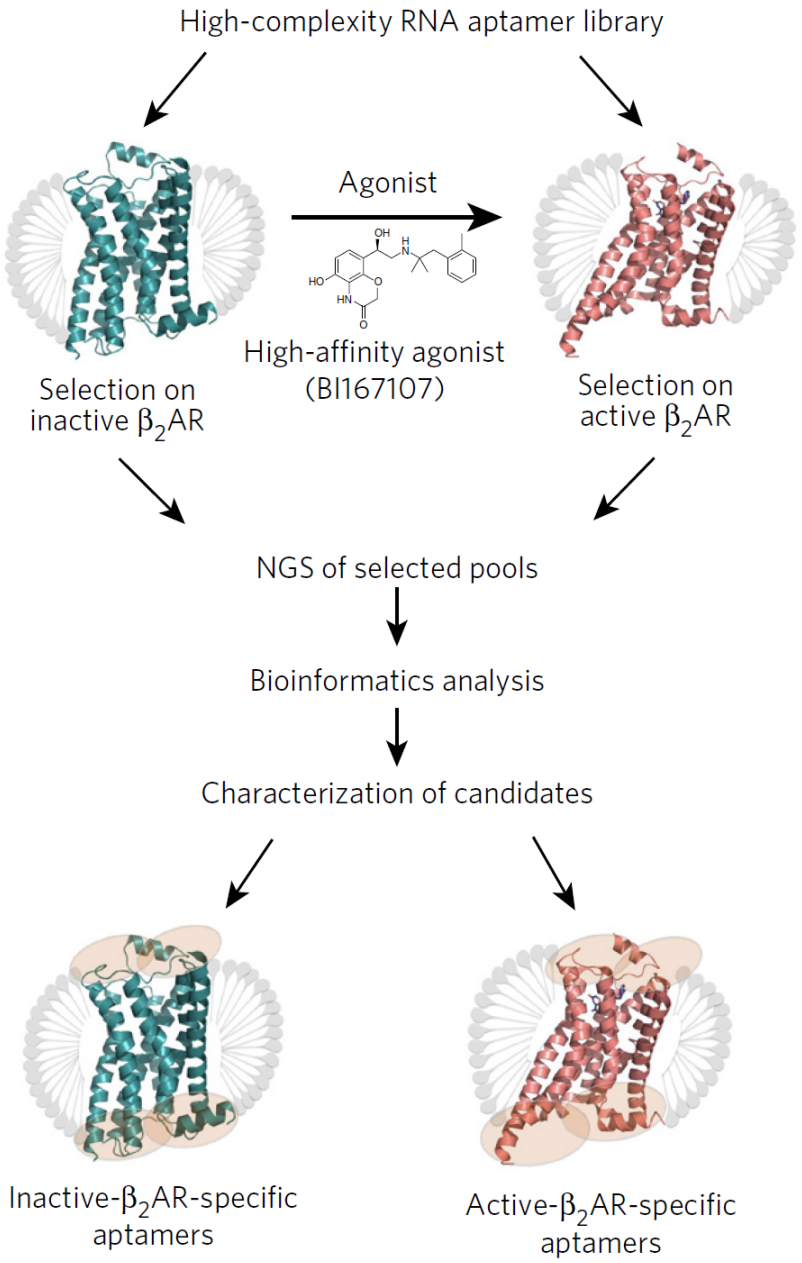
stabilized by MNG (maltose neopentyl glycol) detergent micelles

β_2AR ligand → only isolate functional receptors

Traditional SELEX was supplemented with next-generation sequencing

- 9 rounds of traditional SELEX were done (**twice**; against active and inactive β_2AR).

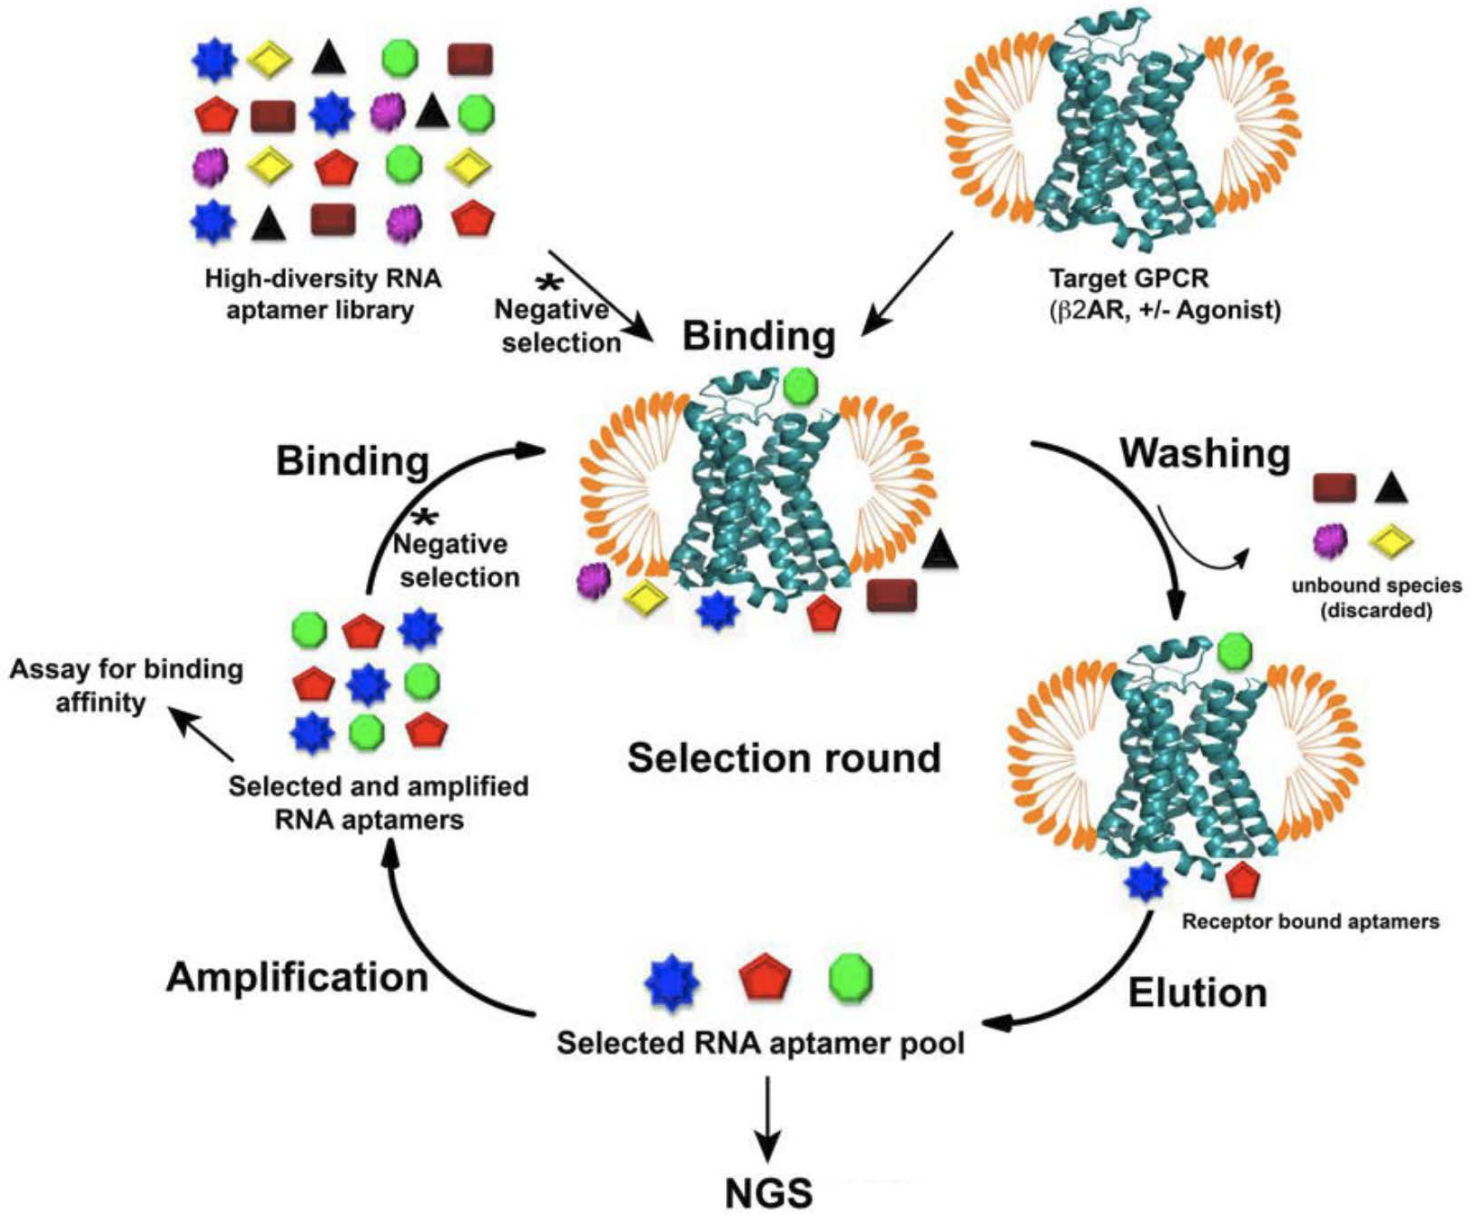
- In each round, aliquots were taken for:
  - Measurement of bulk K_d of the pool
  - Next-generation sequencing → individual species
    - → Not absolute copy number, but **enrichment from early to late** rounds!



The starting library consisted of ~10^{15} unique sequences.

Each had a 40-nucleotide random region, and flanking primer regions

- 15-base on 5’ side
- 25-base on 3’ side



The iterative SELEX process

1. A dsDNA library is **transcribed** *in vitro* to an RNA library overnight
   - Y639F mutant T7 RNA polymerase allows incorporation of 2’-F-pyrimidines

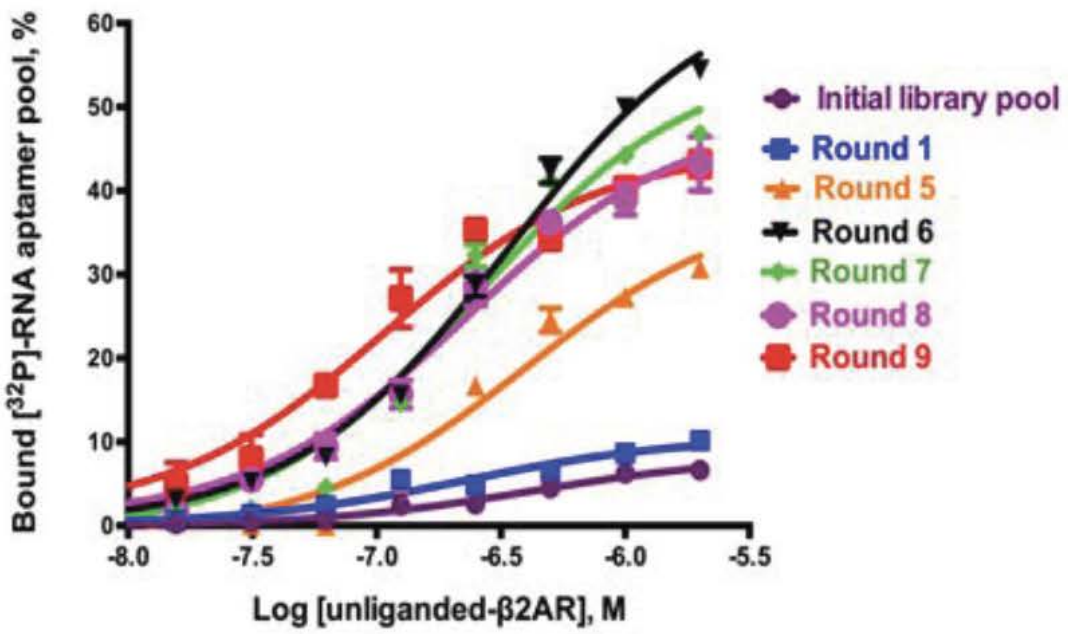
     → nuclease resistance
2. **Selection**
3. ¼ of the RNA pool is **reverse transcribed** to DNA
4. **PCR** amplification

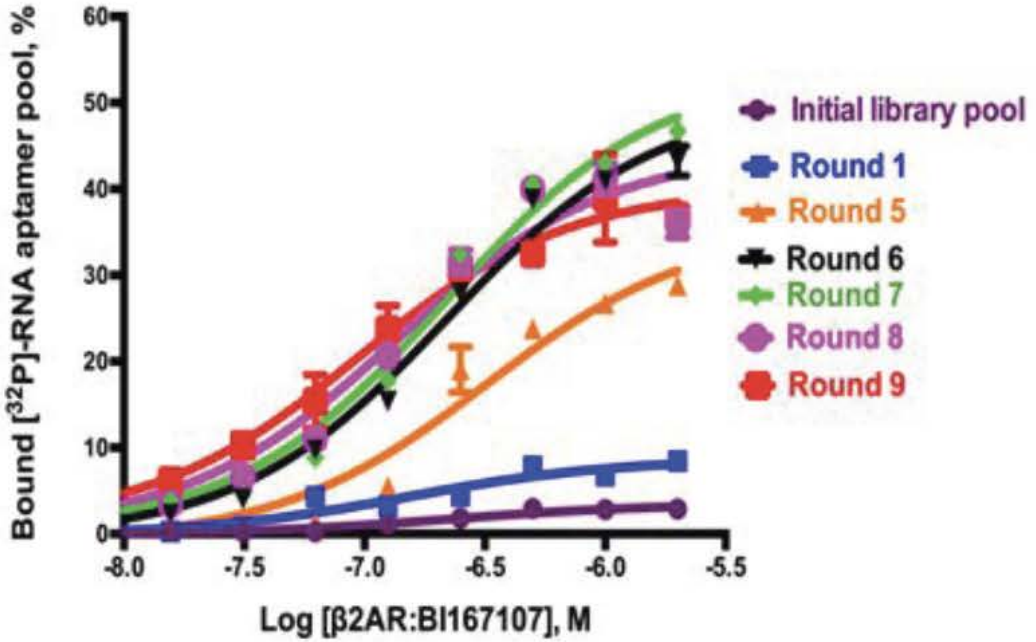
→ repeat

The selection process in detail

1. **Negative selection**: The RNA aptamer mix is incubated with the nitrocellulose matrix (without the target, in selection buffer, at 25°C).
   - Filter-binding aptamers are depleted
   - In the 5th round, negative selection was performed with a nontarget receptor (AT1aR bound to telmisartan).
2. **Positive selection**: aptamers are incubated with β_2AR (ligand-bound or unbound), then passed through nitrocellulose filters.
   - **Unbound aptamers are washed away**, aptamer-β_2AR complexes stick to the matrix.
3. Bound aptamers are extracted (incubated in phenol/chloroform/isoalyl alcohol, chloroform extracted, ethanol precipitated, and resuspended in Tris-EDTA buffer).

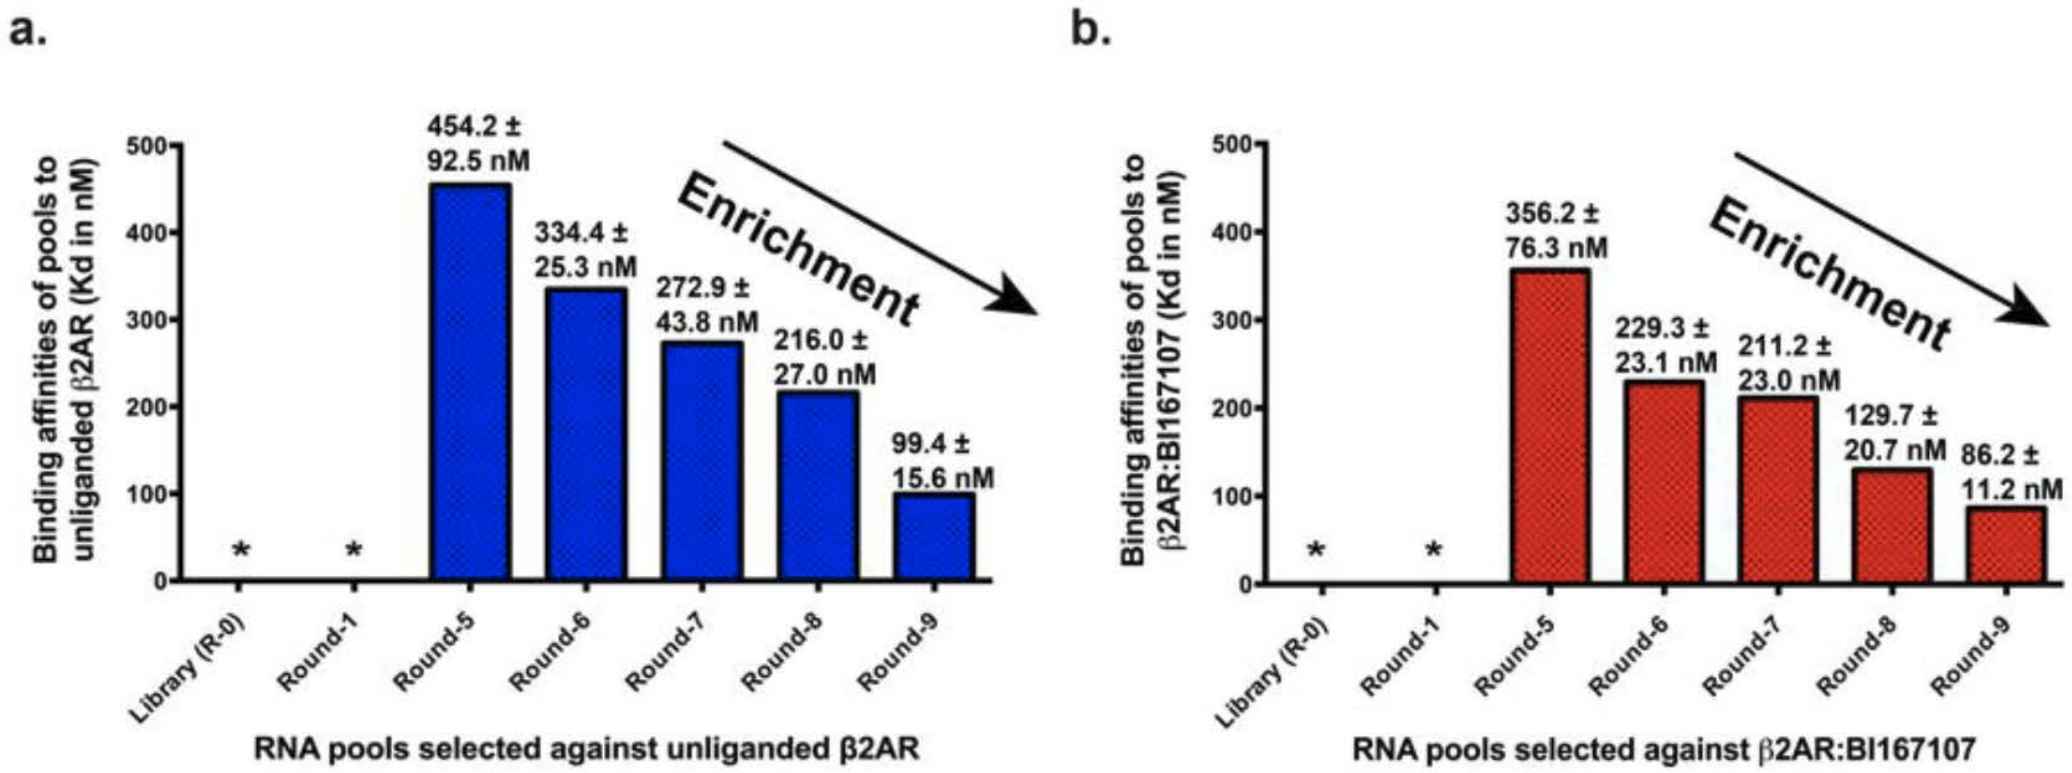
In later rounds, a larger fraction of the aptamer pool bound to the target





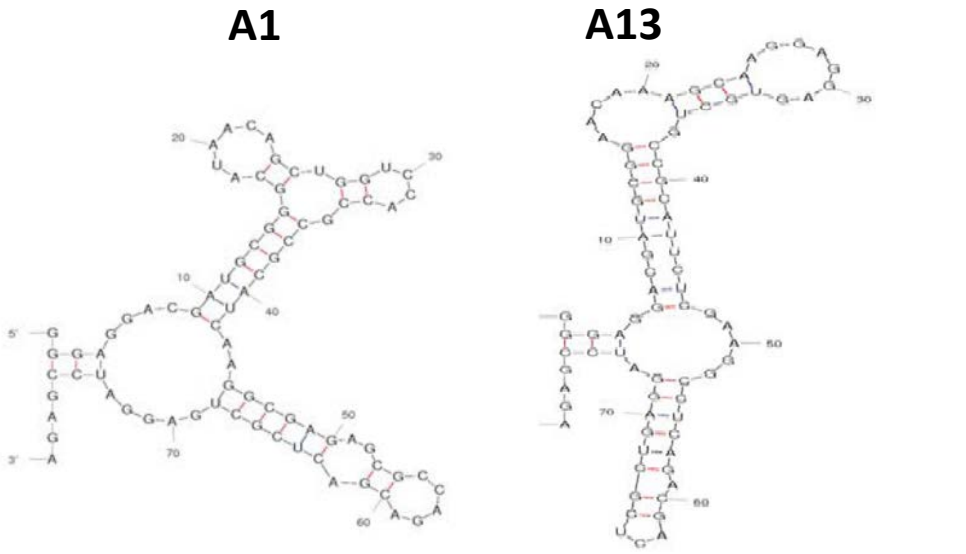
Nitrocellulose filter binding assay with 5’-^{32}P-radiolabelled aptamers

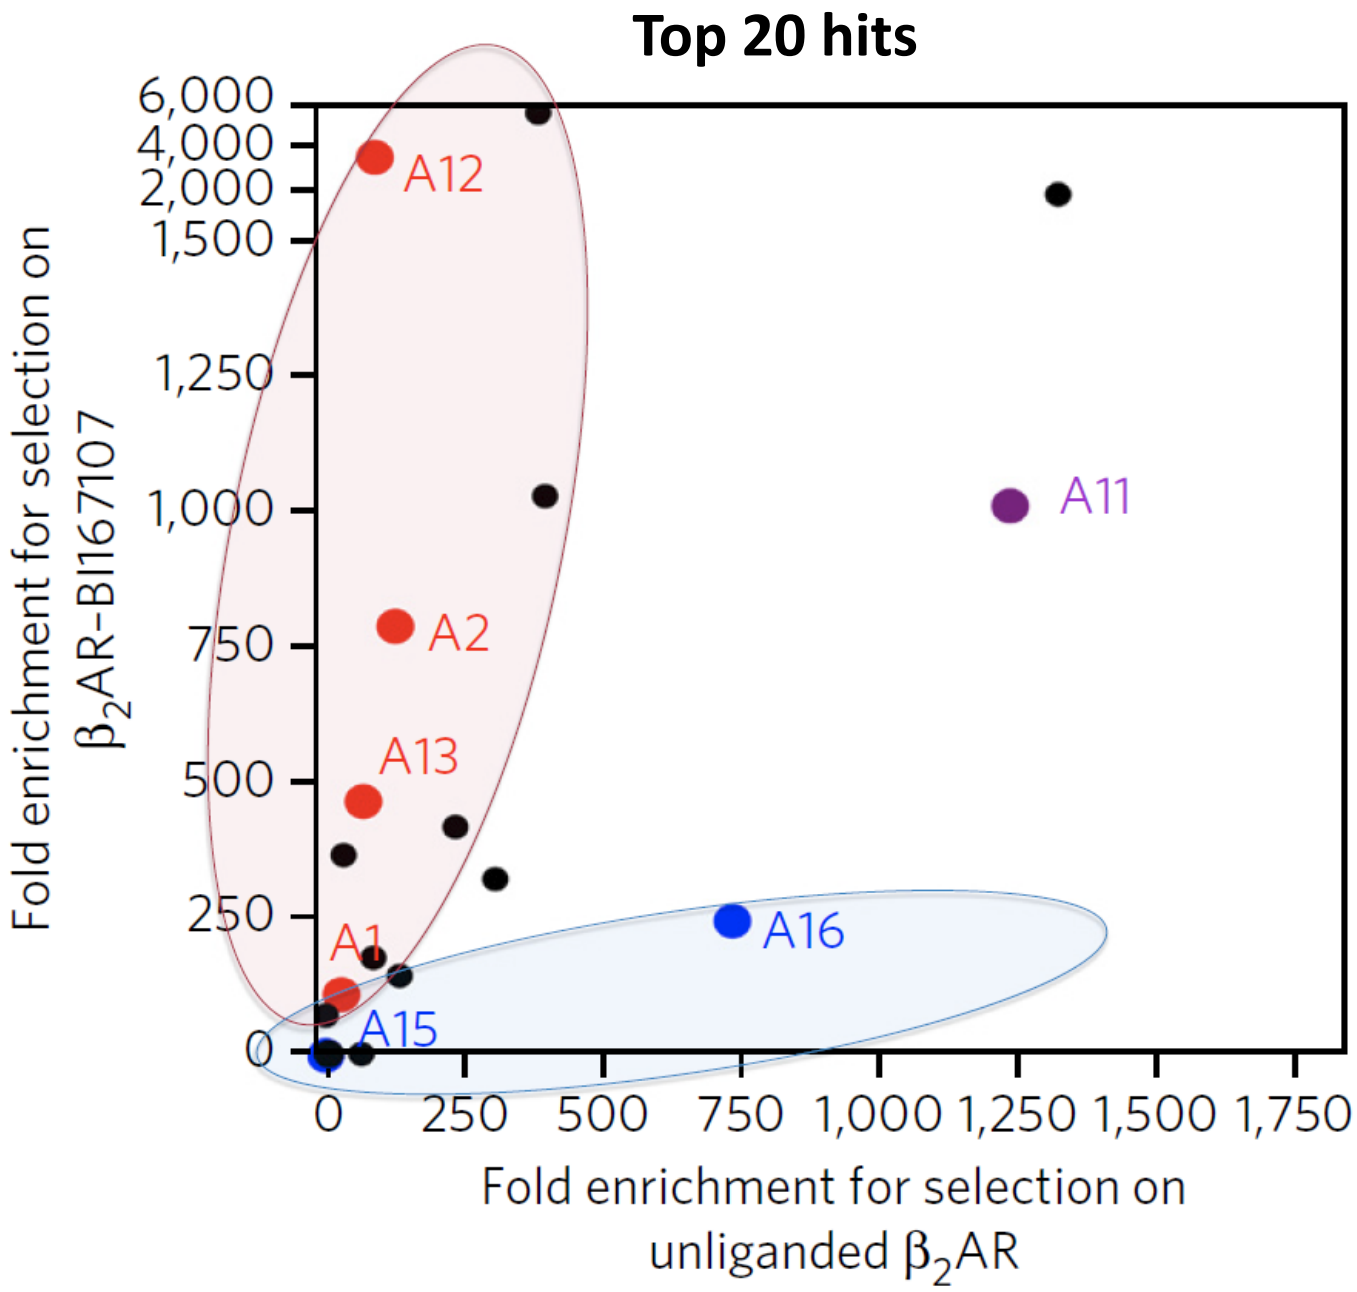
In later rounds, a larger fraction of the aptamer pool bound to the target



A list of top 20 aptamers was compiled

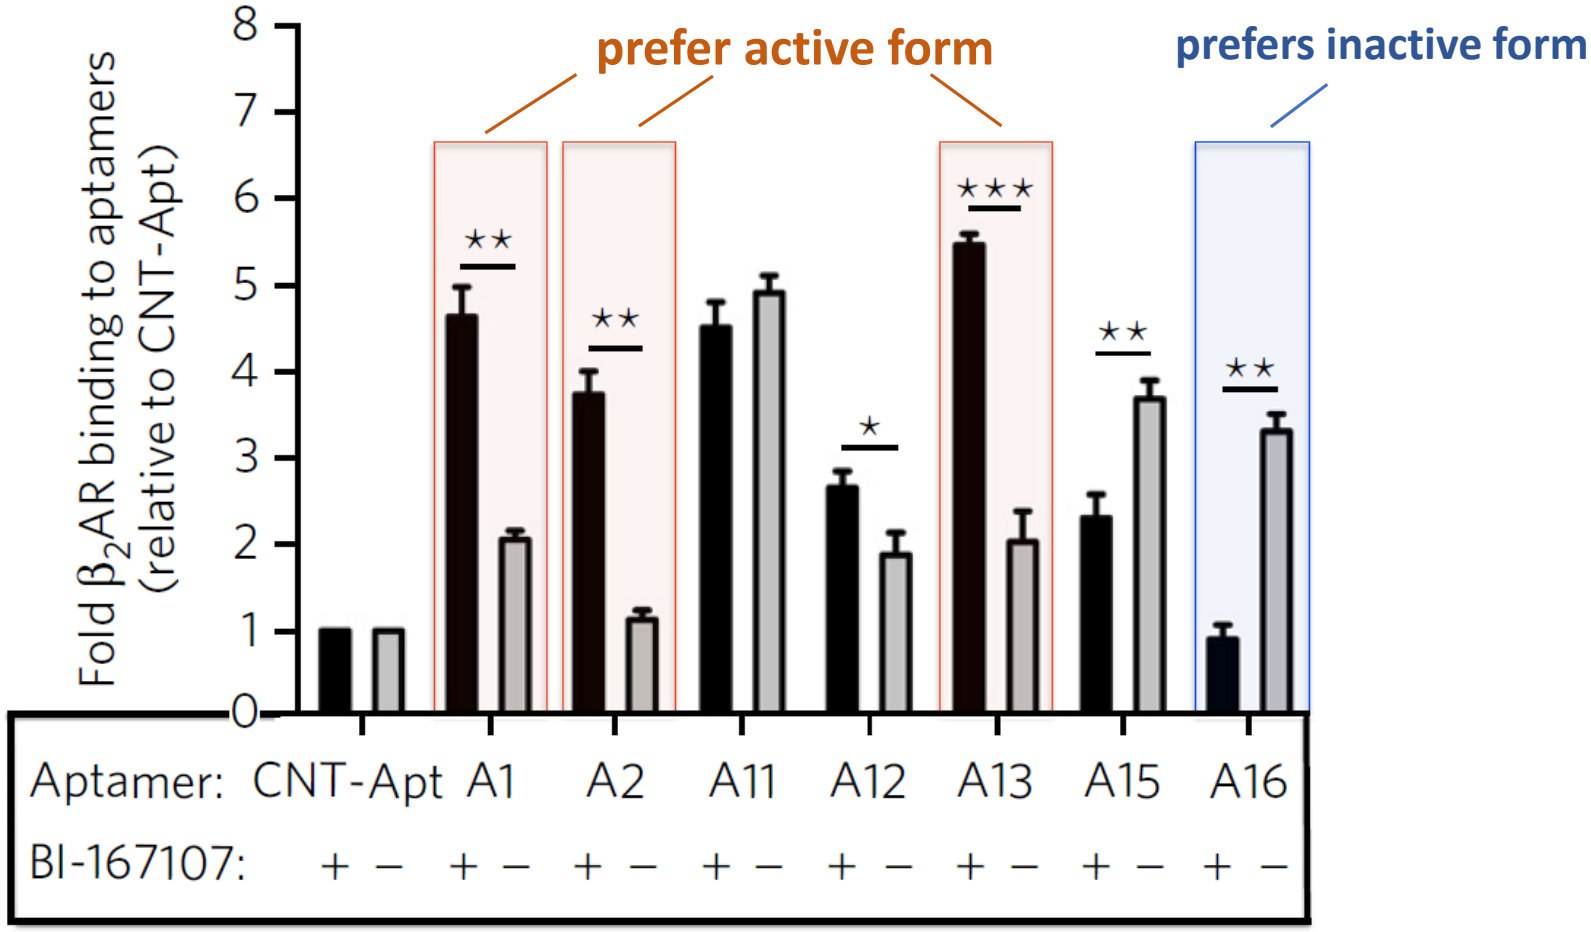
- Samples from multiple rounds were collected for multiplexed Illumina HiSeq 2000
  - PCR was done with primers containing a pool-specific barcode for multiplexing
- Criteria for picking the top species were:
  - **Fold enrichment** in later rounds (ratio of frequency in round 9 vs. round 4)
  - Rank-order copy number
  - Predicted structural stability (from *mfold* RNA folding algorithm)



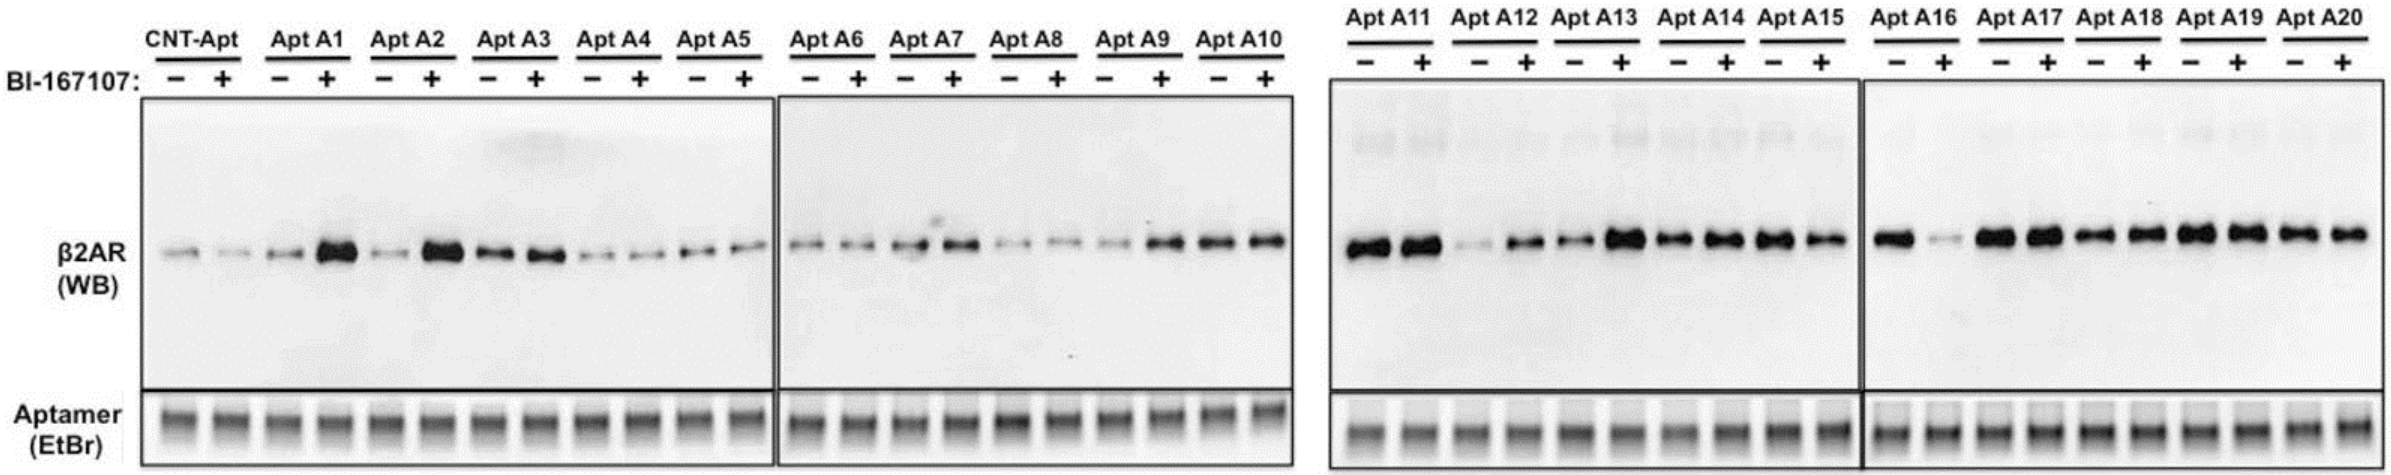


Some aptamers had **high fold enrichment** (in rounds 9 vs. round 4) specifically **for bound or unbound** β_2AR.

A pulldown assay confirmed the predictions from bioinformatics

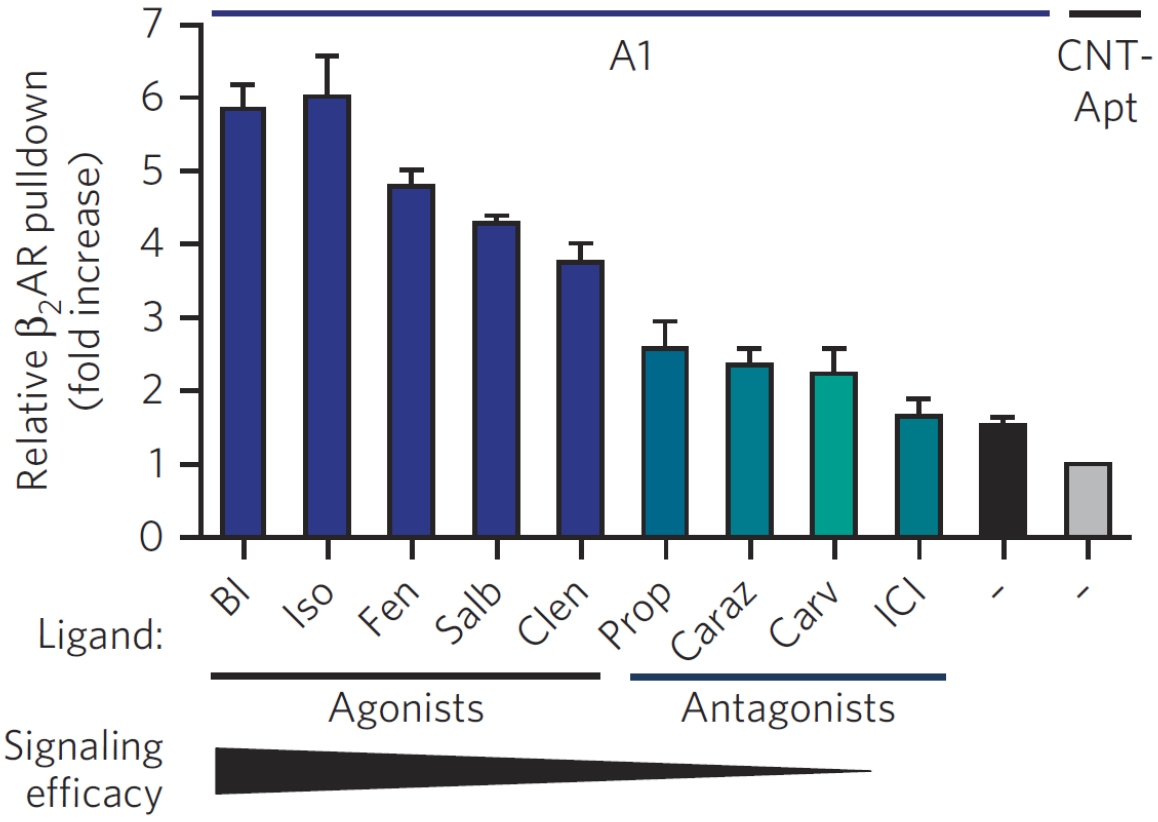


A pulldown assay confirmed the predictions from bioinformatics

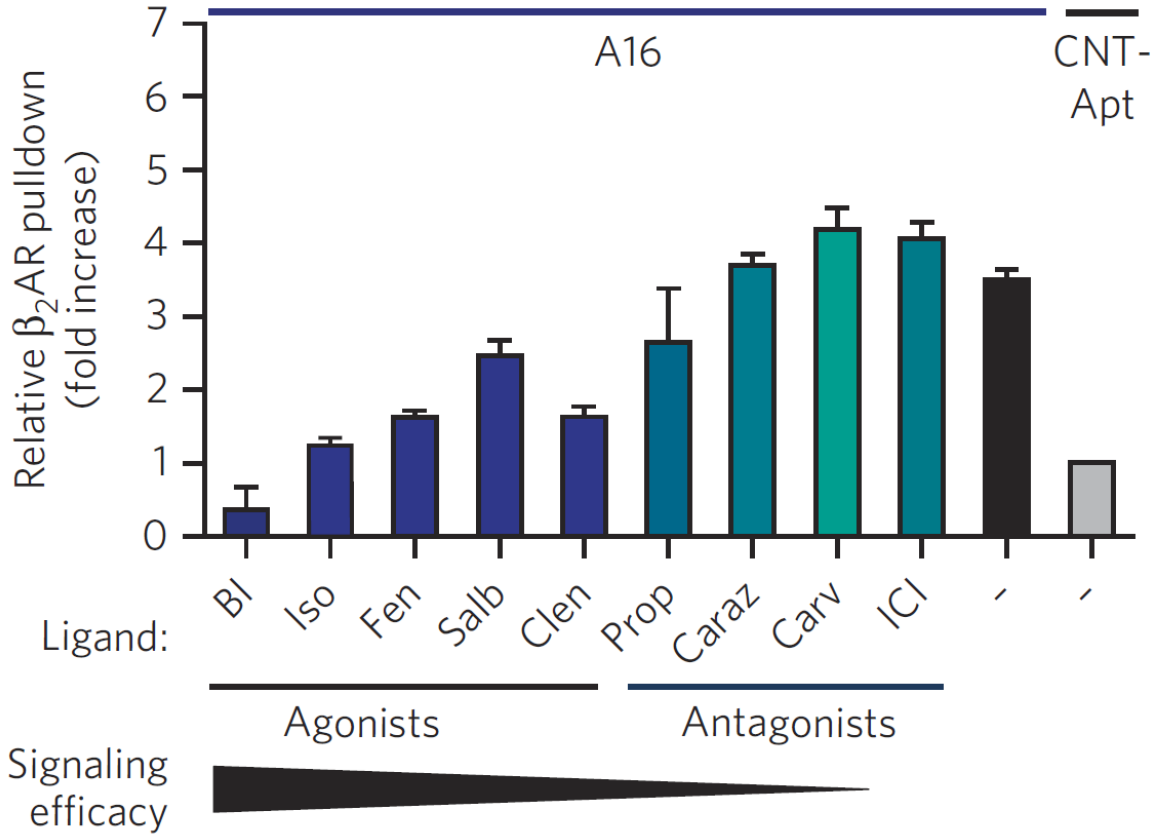


- Biotinylated aptamer species were immobilized onto NeutrAvidin beads, then incubated with β_2AR (± agonist) for 1 hour. Unbound β_2AR was washed away.
- Bound complexes were eluted. Western blot was done using anti-β_2AR antibody.

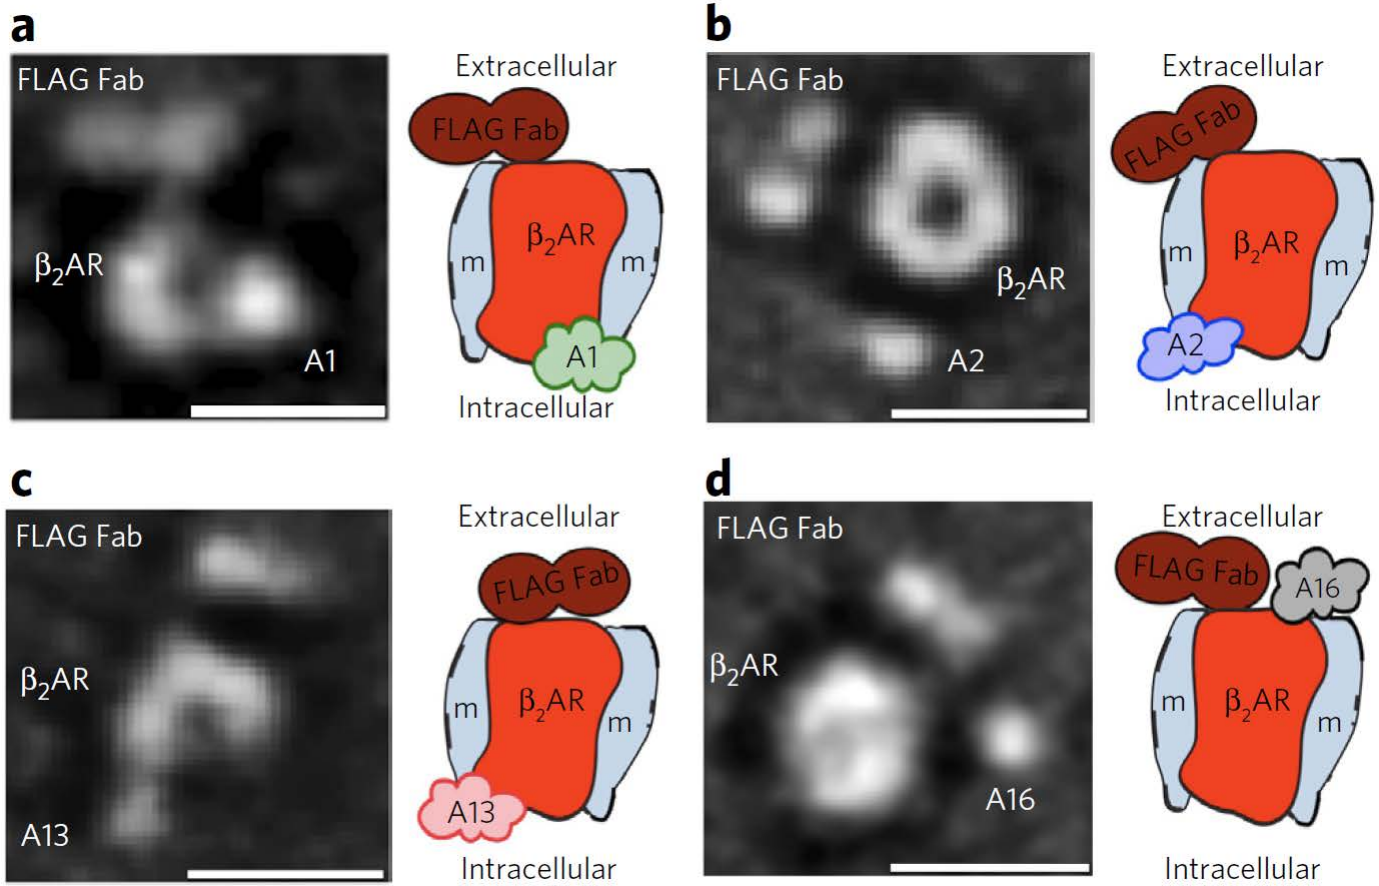
Incubated with A1 aptamer
(stabilizes **active** form)



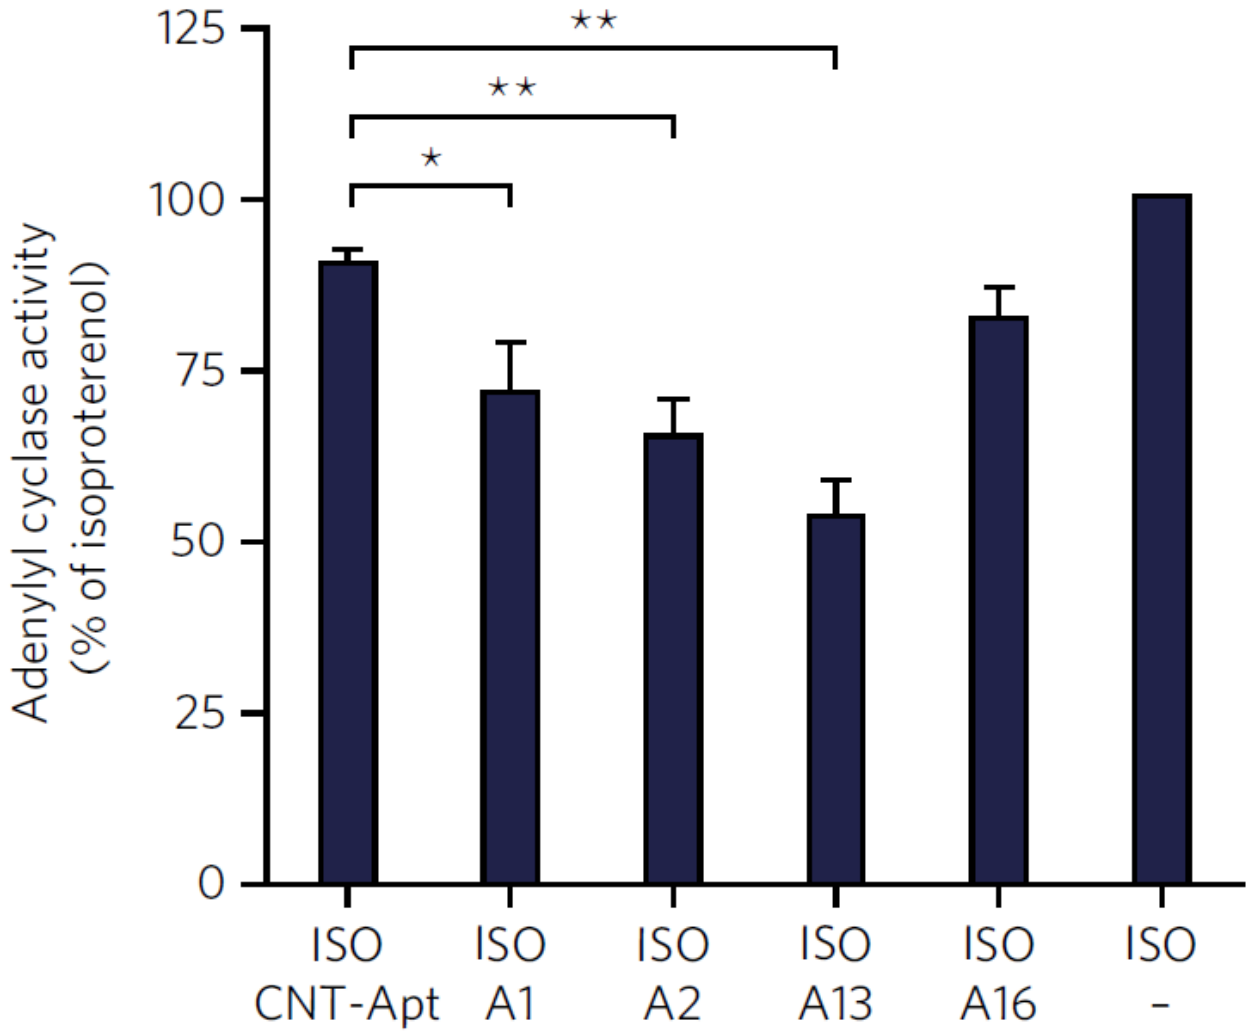
Incubated with A16 aptamer
(stabilizes **inactive** form)



Electron microscopy was used to visualize the binding locations of the aptamers (intra- versus extracellular)



cAMP assay



Paradoxically, the aptamers specific for active β_2AR actually decreased cAMP signalling.

Maybe their intracellular binding sites competed with the G protein?

Conclusions

Conformationally selective RNA aptamers allosterically modulate the β_2-adrenoceptor

- It was possible to create aptamers that preferentially bound to the ligand-bound/active or inactive state of β_2AR.
  - This hold promise for aptamers as GPCR-targeting drugs.

- Next-generation sequencing was useful for identifying RNA species with the desired features.

Cell-SELEX isolates aptamers that bind to specific cells

Tunable cytotoxic aptamer–drug conjugates for the treatment of prostate cancer

Bethany Powell Gray[a], Linsley Kelly[a,b], Douglas P. Ahrens[c], Ashley P. Barry[c], Christina Kratschmer[b], Matthew Levy[b,1], and Bruce A. Sullenger[a,2]

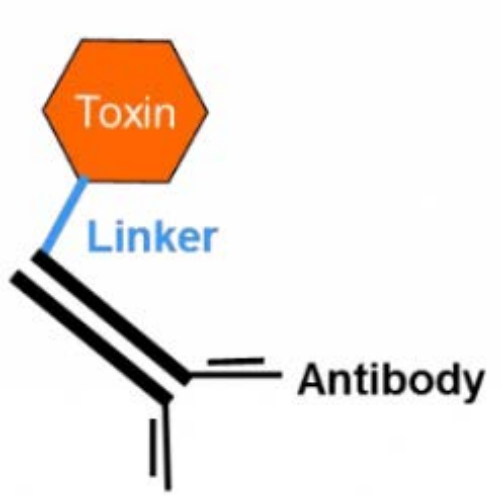
PNAS, 2018

Antibody-drug conjugates permit the use of highly toxic agents

- Antibody-drug conjugates target cancer cells specifically
  - An anti-PSMA-auristatin conjugate is in clinical trials for prostate cancer

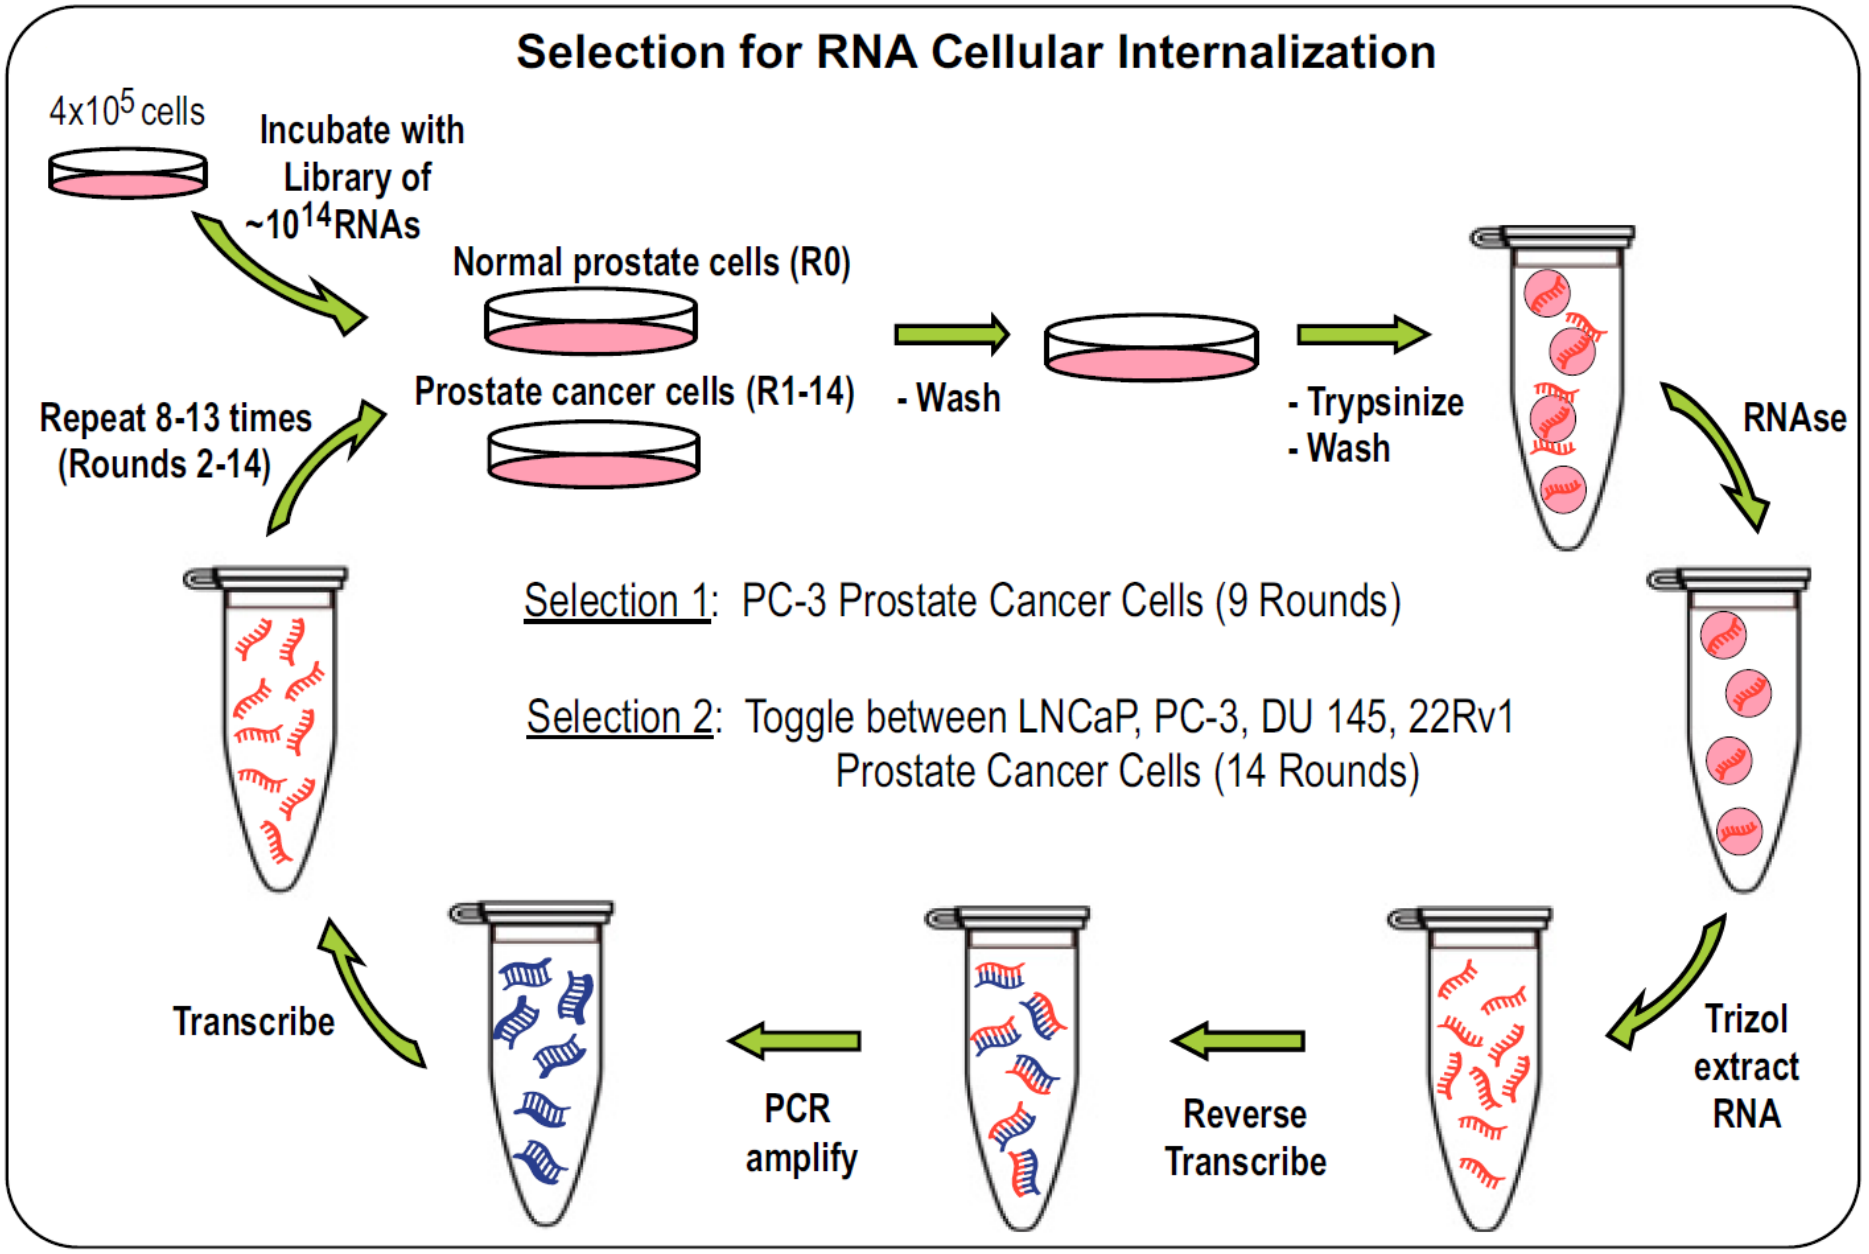
    PSMA = Prostate-specific membrane antigen

    auristatin = antimitotic agent, binds to tubulin



- Additional targets and better specificity would be desirable.
- Cell-SELEX can be used to design new **aptamer-drug conjugates**.

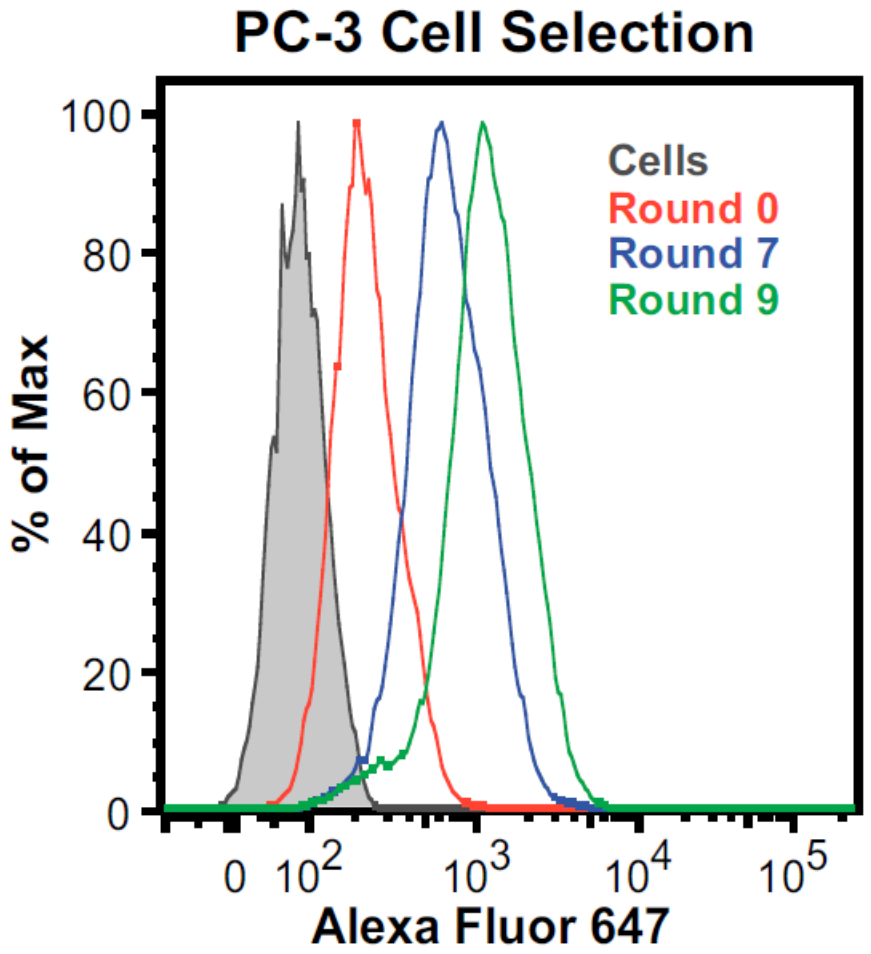
2’-F modified RNAs



Some cell lines were PSMA-negative (PC-3 & DU 145)

Flow cytometry reveals progressively better internalization of the RNA aptamer pool

RNA pools from different selection rounds were transcribed with a 3’ 22 nt tail that annealed to an Alexa Fluor 647-labeled reverse primer.



Of 12 unique RNAs that were evaluated, 3 were able to internalize.

The **E3 aptamer** showed the best internalization.

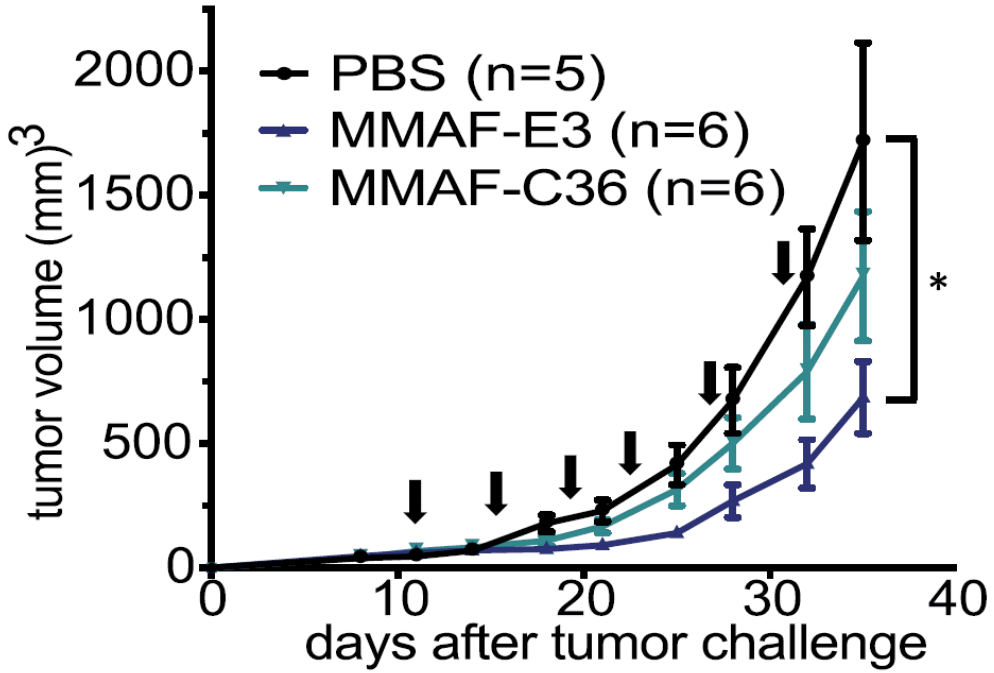
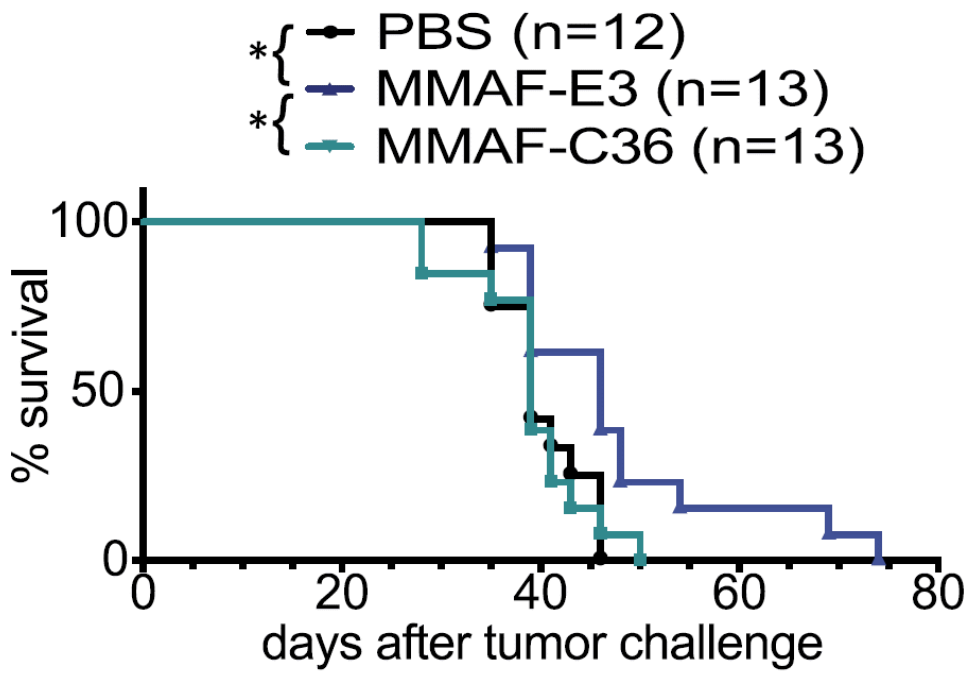
The conjugate showed **anti-tumor efficacy** *in vivo*



***p* = 0.03**



***p* = 0.02**

Conclusions

Tunable cytotoxic aptamer–drug conjugates for the treatment of prostate cancer

Bethany Powell Gray[a], Linsley Kelly[a,b], Douglas P. Ahrens[c], Ashley P. Barry[c], Christina Kratschmer[b], Matthew Levy[b,1], and Bruce A. Sullenger[a,2]

- A promising aptamer-drug conjugate was produced through cell-internalization SELEX.
  - Further optimisation of the half-life may increase efficacy in vivo.

- No attempt was made to find the target molecule or complex recognized by the aptamer.

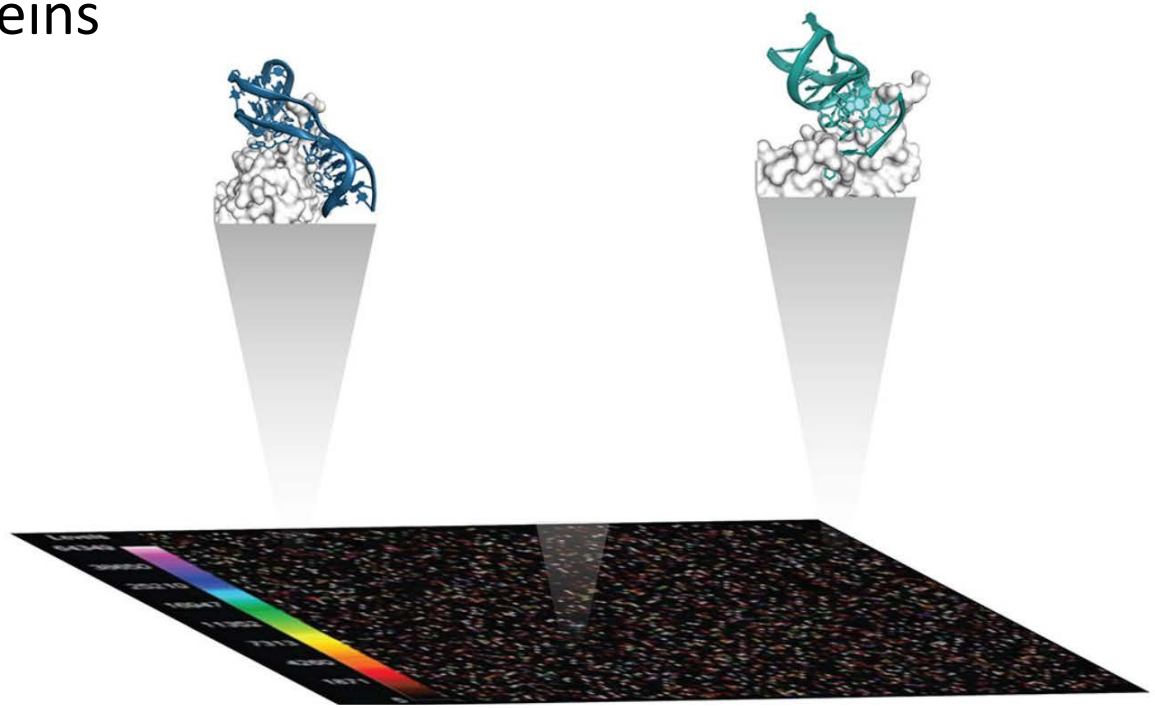
Nature, June 2018

Proteomics was done using SOMAscan®,

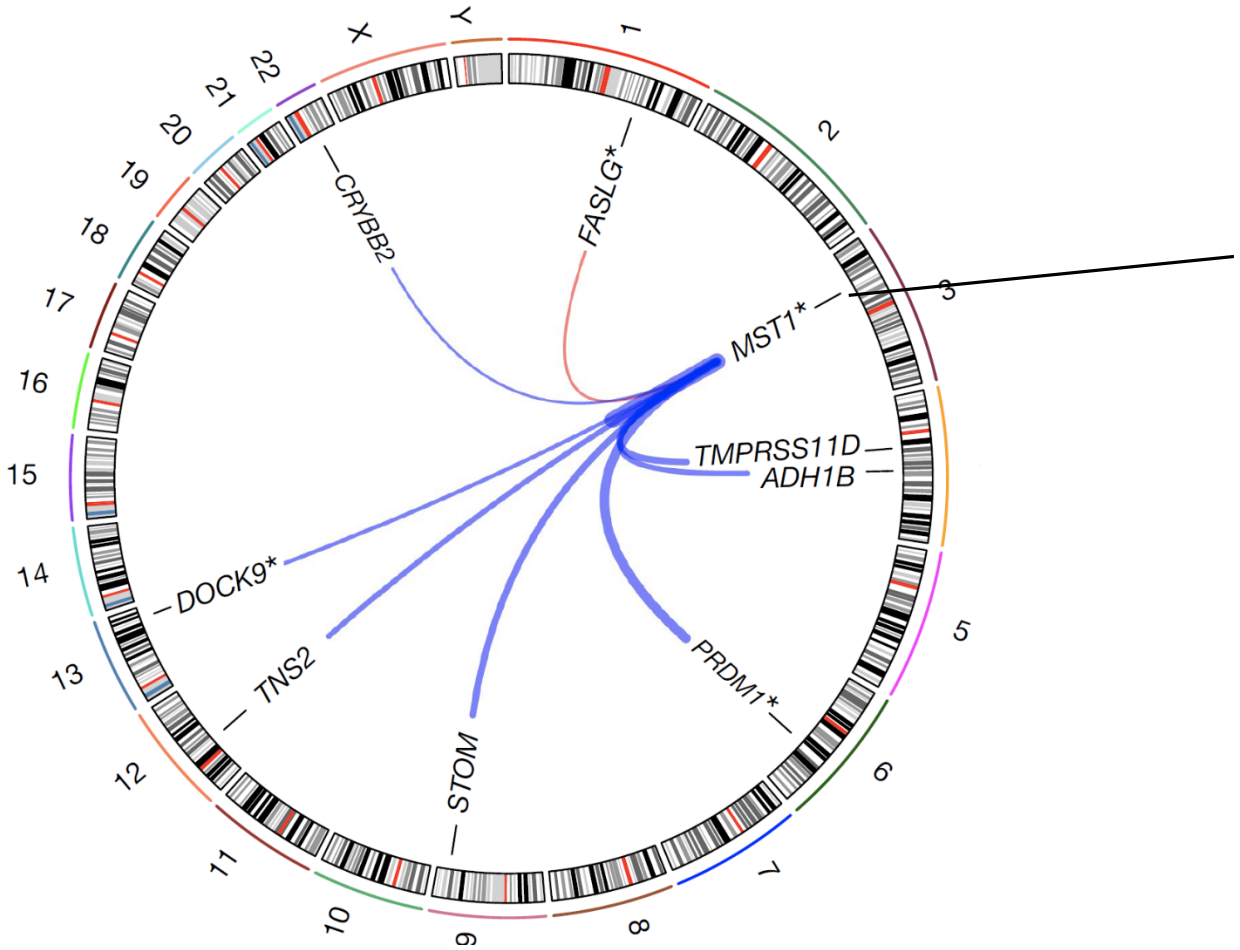
an assay based on chemically modified aptamers.

The SOMAscan assay contains aptamer species against thousands of protein targets

- In a multi-step process, stable aptamer-protein complexes are isolated, and unbound proteins and aptamers are washed away.
- The aptamer component of the complex is quantified using a fluorescence-based microarray chip.



Both SOMAscan (proteomics → 3622 plasma proteins) and a SNP microarray (genetics) was done for 3622 healthy blood donors



The rs3197999:A variant, located in the macrophage-stimulating 1 (*MST1*) gene, is known to be associated with inflammatory bowel disease.

This locus was associated with the plasma protein levels of 8 proteins (including MST1).

Thank you for your attention!
